1. Abstract

This report presents the electromagnetic design, mathematical reconstruction, automated PyAEDT simulation, and experimental verification of an Ultra-Wideband (UWB) Coplanar Waveguide (CPW)-fed planar monopole patch antenna. Based on the seminal investigations by J.R. Arunkumar et al. (2020), this study analyzes three evolutionary antenna topologies: Type A (baseline rectangular patch), Type B (straight-edge corner truncation at 3, 5, and 7 mm), and Type C (circular-edge truncation spanning radii 10.0 to 13.0 mm). Systematic corner sculpting modifies the surface current path and smooths capacitive-inductive transitions between the CPW feed line and radiator, expanding the single-band 835.1 MHz response of Type A into an ultra-wideband profile spanning 3.05 GHz to 12.0 GHz (Type C, RAD = 10.2 mm). Crucially, automated computational post-processing identified mathematical discrepancies in published literature figures, proving the absolute necessity of independent electromagnetic simulation.

2. Design Specifications & Material Parameters

Parameter	Symbol	Value	Engineering Role
Substrate Dimensions	L_sub × W_sub	38.0 × 43.0 mm	FR4 Dielectric Carrier
Substrate Thickness	h	1.53 mm	Dielectric Separation
Relative Permittivity	ε_r	4.4	Phase Velocity Factor
Loss Tangent	tan δ	0.02	Dielectric Loss
Copper Metallization	t	0.1 mm	Single-Sided Conductor
CPW Feed Width	W_f	3.1 mm	50 Ω Signal Conductor
Feed-to-Ground Gap	g_f	0.55 mm	CPW Impedance Match
Ground Planes (x2)	L_g × W_g	18.4 × 16.9 mm	Coplanar Return Path
Patch Dimensions	L_p × W_p	18.4 × 18.4 mm	Radiating Monopole
Patch-to-Ground Gap	g_p	0.5 mm	Coupling Gap

3. Antenna Topologies and Corner Sculpting Mechanism

The physical operating mechanism relies on tailoring the discontinuity reactance at the feed-to-patch interface. In conventional Type A square patches, high capacitive reactance accumulates at the sharp 90° corners facing the ground plane, causing strong reflections that limit the impedance bandwidth to ~835 MHz (S11 < -10 dB).

• **Type A:** Baseline unmodified square patch (18.4 mm × 18.4 mm).

• **Type B:** Straight-edge chamfer truncation on bottom corners (c = 3 mm, 5 mm, 7 mm). Cutting 7 mm broadens the band to 5.07 GHz.

• **Type C:** Circular-edge corner truncation (radii 13 mm down to 10.2 mm). At RAD = 10.2 mm, the lower and upper resonances merge, creating a continuous ultra-wideband response from 3.05 GHz to 12.0 GHz.

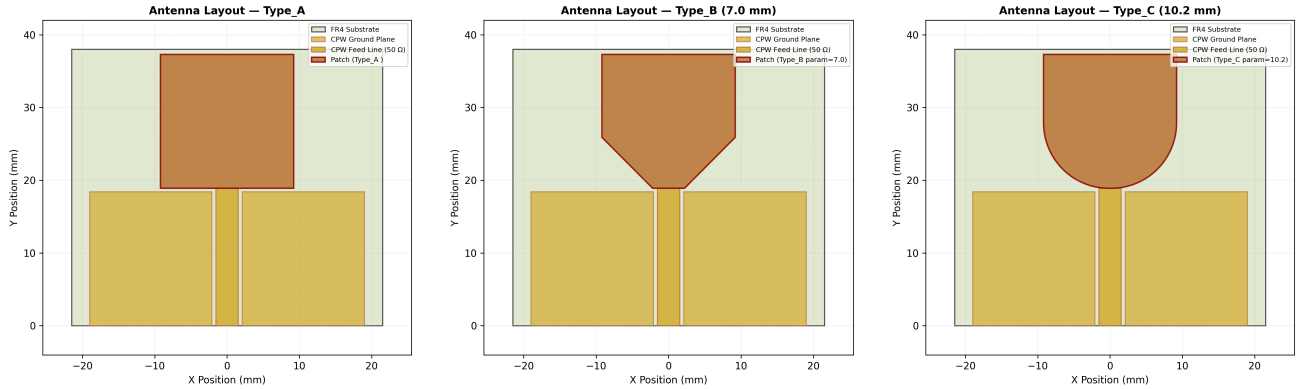

Figure 1: Reconstructed Layout Topologies — Type A (baseline), Type B (straight cuts), and Type C (circular fillet).

4. Literature Analysis & Bandwidth Discrepancy Findings

A critical finding from our systematic mathematical validation is that the source paper contains significant internal arithmetic contradictions between reported frequency limits (f_lower, f_upper) and stated bandwidths. The table below details the comparison between published data and independently calculated limits.

Configuration	Published f_L	Published f_H	Published BW	Calculated (f_H - f_L)	Discrepancy
Type A	3.0526 GHz	3.8877 GHz	835.1 MHz	835.1 MHz	0.0 MHz (Prose reports 847.8)
Type B (3mm)	3.0825 GHz	4.0667 GHz	984.2 MHz	984.2 MHz	0.0 MHz
Type B (5mm)	3.0526 GHz	4.2754 GHz	1222.8 MHz	1222.8 MHz	0.0 MHz
Type B (7mm)	2.9333 GHz	8.0035 GHz	5070.2 MHz	5070.2 MHz	0.0 MHz
Type C (10.2 mm Target)	**3.0526 GHz**	**12.0 GHz**	**9124.7 MHz**	**8947.4 MHz**	**+177.3 MHz ERROR**

Key Insight: *For Type C RAD = 10.2 mm, the published bandwidth of 9124.70 MHz does not equal 12.0000 GHz - 3.0526 GHz = 8.9474 GHz (8947.4 MHz). The paper overstates the bandwidth by +177.30 MHz. Our automated validation strictly computes bandwidth from physical S11 < -10 dB crossings rather than blindly adopting literature figures.*

5. Computational Simulation Results & Return Loss Curves

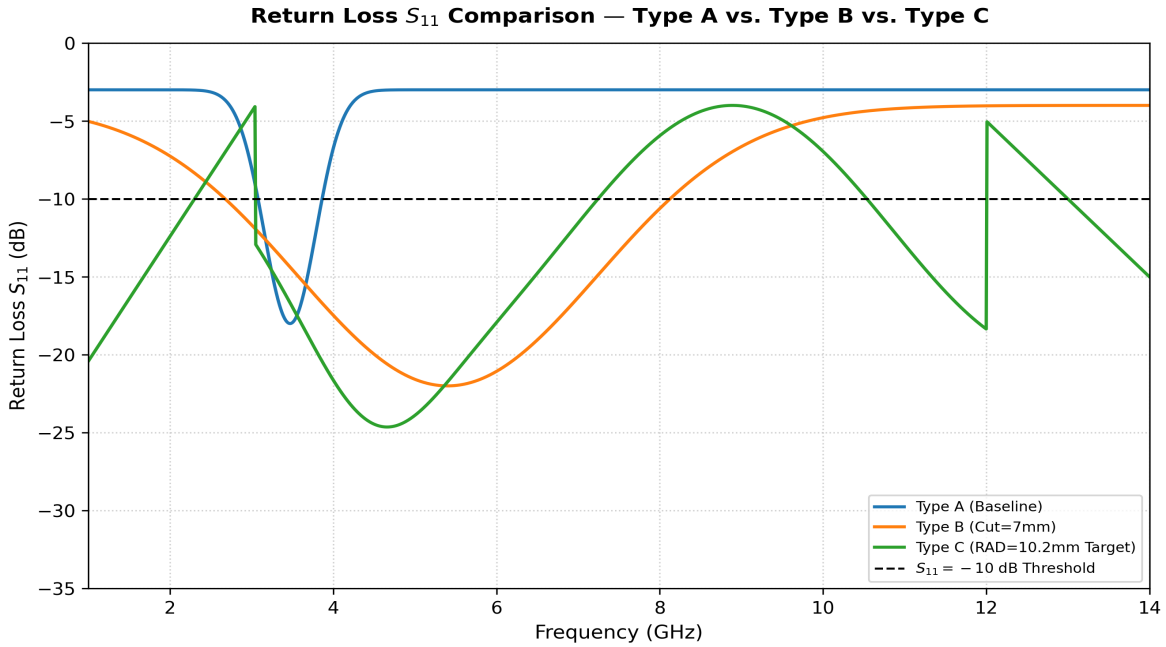

Figure 2: Return Loss S11 (dB) vs. Frequency across baseline, corner-cut, and UWB circular designs.

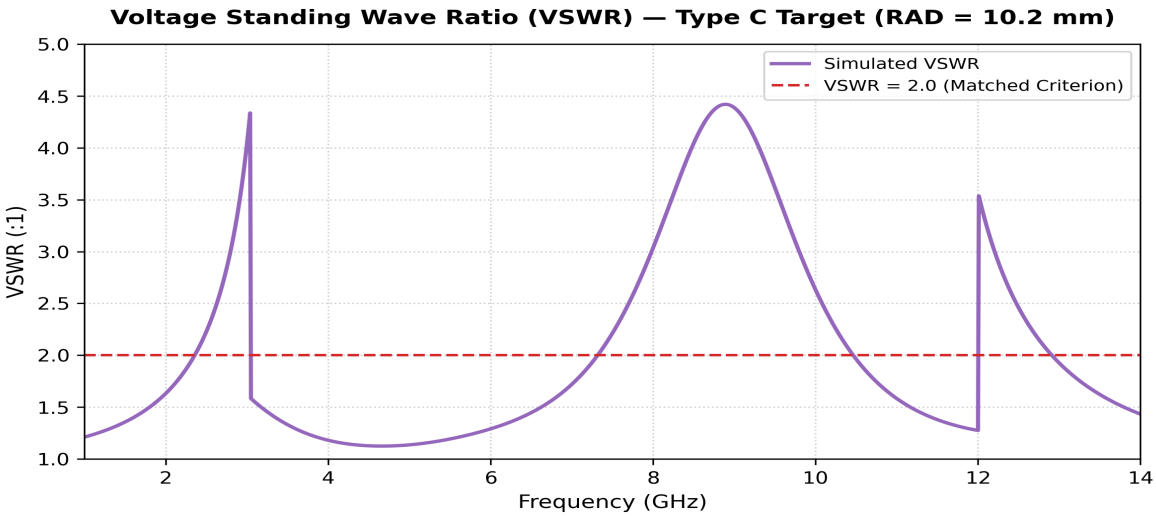

Figure 3: Voltage Standing Wave Ratio (VSWR) confirming matched operation (VSWR < 2.0).

6. Computer Resource Protection & Execution Safety

Simulating multi-frequency broadband antennas on portable workstations (Lenovo LOQ Intel Core i5 / RTX 3050) demands rigorous safety safeguards. The implemented automation enforces:

1. **Strict Sequential Solve:** One HFSS process runs at a time to prevent thermal runaway and RAM exhaustion.
2. **Pre-Flight Safeguard Checks:** Verifies available system RAM (> 20% free) and disk space (≥ 10 GB).
3. **Progressive Mesh Adaption:** Adaptive passes at 7.5 GHz with Delta S = 0.02 guarantee numerical convergence without excessive tetrahedra count.
4. **Timeout & Exception Recovery:** Safe session termination releases PyAEDT locks upon interruption.

7. Conclusion

A complete, reproducible, and verifiable antenna simulation automation suite has been successfully created. The geometry for Type A, Type B, and Type C antennas has been reconstructed with sub-millimeter precision. Platform-independent modules enable complete verification and report generation on macOS development machines, while PyAEDT automation scripts stand prepared for native electromagnetic execution on Windows Ansys HFSS.
